

TANTIFY

Production Decision Companion for Small Food Businesses

TURN TANTSA INTO BETTER PRODUCTION DECISIONS.

Guess Less. Prepare Smarter. Earn More.

One-sentence concept

Tantify helps small prepared-food businesses decide what to prepare, how much to prepare, and when to prepare it using sales history, confirmed orders, available ingredients, batch constraints, and budget - then learns from actual outcomes to improve the next decision.

Name logic: tantsa + quantify - turning rough judgment into measurable production decisions.

The problem Small food businesses commit ingredients, labor, time, and cash before exact demand is known. Too much becomes leftover value; too little becomes a stockout and missed sale.

Core question

"Given what I know today, what should I prepare next?"

Tantify is	Tantify is not
A daily production-planning companion	A generic POS replacement
A low-data decision layer for small food businesses	A guaranteed AI forecaster
Merchant-controlled and explainable	A food-safety certification
Able to start with simple records	Dependent on enterprise integrations from day one
Focused on what, how much, and when to prepare	A consumer surplus marketplace at launch

Competition fit: Food Security / AI for Food Systems

Measurable claim: reduce avoidable prepared-food loss and improve production decisions - not "solve hunger."

1. The Problem

A repeated operating decision with financial consequences

- Overproduction - too much food is prepared before demand is known, tying cash up in unsold items.
- Stockouts - too little is prepared, products sell out early, and potential sales are missed.
- Guess-based planning - owners may rely on memory, habit, notebooks, or rough estimates.
- Fragmented information - sales, preorders, leftovers, stockouts, ingredients, batch sizes, and cash limits are rarely combined into one decision.
- Late reaction - slow sell-through may only be noticed near closing, when recovery options are weaker.
- Working-capital pressure - the owner may have a fixed amount of cash available for tomorrow's ingredients.

Formal problem statement

Small prepared-food businesses make production decisions under uncertain demand and resource constraints. This can lead to avoidable overproduction, stockouts, and inefficient use of working capital. They need an accessible way to turn simple business records into practical, explainable preparation decisions.

Human story

The owner commits part of tomorrow's livelihood before knowing tomorrow's demand.

What existing evidence supports

Evidence	What it supports	What it does not prove
PSA: 37,500 formal accommodation/food-service establishments in 2024; 27,638 restaurant/mobile-food-service businesses [S1]	The sector is economically significant.	Not every establishment has Tantify's pain.
Davao Region establishment data previously reviewed [S2]	A microbusiness-first local approach is relevant.	It does not prove willingness to pay.
Philippine food-service research on overproduction/spoilage [S3]	The pain mechanism is documented.	It does not quantify typical Tagum losses.
Local bakery operations research on forecasting/scheduling [S4]	Production planning is an established operational need.	It does not validate Tantify itself.

Evidence boundary: secondary sources are not merchant interviews. Local loss frequency, peso impact, and willingness to pay still require validation.

2. Target Market

Defined by operating behavior, not by one business type

Best-fit behavior

Small prepared-food businesses that repeatedly produce before exact demand is known, have a limited selling window, and can measure what they produced, sold, and had left.

Segment	Why it may fit	Main challenge	Priority
Panaderias / small bakeries	Repeat SKUs, batches, clear counts, leftovers and early sellouts	Experienced owners may already have strong routines	High
Carinderias	Daily preparation decisions; strong working-capital sensitivity	Changing menus, portions, and food-safety complexity	High
Food stalls / kiosks	Short selling windows; fluctuating place/time demand	Weather and event volatility	High
Small cafes	Pastries/sandwiches and time-of-day demand	More existing POS competition	Medium
Made-to-order sellers	Costing still useful	Demand is mostly committed; lower leftover pain	Low
Restaurant chains	Potential savings at scale	Enterprise integrations and strong incumbents	Later

Ideal customer profile

- Produces repeatable items several days per week.
- Makes at least part of production before all demand is known.
- Experiences recurring leftovers, late discounting, or stockouts.
- Can record simple daily totals or import them later.
- Owner/operator controls production quantity and pricing.
- Has enough volume that a small monthly fee could be justified by measurable value.

Go-to-market rule

Interview several segments first. Pilot with the segment where the pain is frequent, expensive, measurable, and practical to record. Do not force bakeries if another segment shows stronger repeat losses.

3. How Tantify Works

One continuous daily decision loop

Stage	Input	Output / decision
1. Record	Recent sales, production, leftovers, stockouts, preorders	Usable operating history
2. Plan	History + budget + ingredients + batch/capacity constraints	Recommended quantity / range + reasons
3. Approve	Owner judgment	Accepted or adjusted plan
4. Monitor	Midday stock or transaction update	Updated sell-through picture
5. Act	Remaining stock + remaining time	Next-batch, delay, bundle, markdown, or hold decision
6. Review	Actual outcome + override reason	Next-cycle learning and value review

Core product logic

Plan before production. Reassess before waste. Learn after every selling cycle.

Illustrative bakery scenario

Input / event	Example
Normal quantity	120 pieces
Estimated walk-in demand	72 pieces
Confirmed preorders	12 pieces
Batch size	12 pieces
Tantify plan	84 pieces total, with staging if practical
Initial action	Prepare 60 pieces; reserve committed orders
Checkpoint	Reassess the remaining 24 after a stock update
If sales are faster	Suggest another batch if ingredients and selling time allow
If sales are slower	Delay/cancel the next batch; consider an eligible recovery action
Closing	Record normal sales, markdown sales, unsold, discarded, and sold-out timing

All quantities above are illustrative, not pilot results.

4. Core Features

The production recommendation remains the center

Feature	What it does	Business value
Quick daily records	Made, sold, remaining, discarded, sold out	Creates usable history
Production recommendation	Suggests quantities within demand, batch, ingredient, capacity, and budget constraints	Balances excess and stockout risk
Confirmed preorder tracking	Separates committed demand from expected walk-ins	Protects commitments without double-counting
Kasya sa Puhunan	Plans quantities within an ingredient-purchasing budget	Allocates limited working capital
Batch timing guidance	Suggests what to prepare first and when to reassess another batch	Reduces premature production
Midday stock update	Uses current remaining stock or imported transactions	Enables intraday recommendations
Leftover recovery	Suggests eligible owner-approved bundles, markdowns, donation/disposal	Creates a recovery path before closing
Outcome review	Shows production, sales, waste, stockouts, contribution, overrides	Tests whether decisions are improving

Signature feature: Kasya sa Puhunan

"May P1,500 akong pambili bukas. Ano at ilan ang kaya kong ihanda?" Tantify considers on-hand ingredients, current ingredient costs, menu/recipes, confirmed orders, estimated demand, batch sizes, capacity, and expected contribution, then proposes a feasible production mix.

- If the usual quantity of every product exceeds the budget, Tantify can preserve confirmed orders while reducing lower-confidence items.
- On-hand inventory reduces tomorrow's cash purchase requirement but still has an economic cost; the app must keep cash requirement and product cost separate.
- For fixed-product bakeries, batch quantity and timing may matter more than budget optimization; the product should adapt to the segment.

5. Technology, Low-Data Behavior, and Safety

Use AI only where it adds practical value

Technology	Role	What must be demonstrated
Multimodal AI	Turns voice notes or photographed handwritten records into draft entries	Accurate extraction with owner confirmation
Demand forecasting	Estimates likely demand and uncertainty	Improves on owner/simple baselines in real use
Constrained optimization	Finds feasible quantities under budget, ingredient, batch, and capacity limits	Correct, explainable calculations
Intraday forecasting	Updates expectations after a stock/sales checkpoint	Useful decisions from fresh enough data
Explanation generation	Explains why the plan changed	Explanation matches the underlying calculation

AI boundary

Costs, quantities, financial results, and safety status must come from structured data, explicit rules, and validated logic. A language model should not invent them.

Cold-start behavior

Data available	Appropriate behavior
No sales history	Use owner baseline, confirmed orders, and known constraints. No fake confidence.
Limited history	Use comparable-day averages and clearly show uncertainty.
More reliable history	Evaluate forecasting against owner decisions and simple baselines.
Missing/stale midday data	Request an update before giving an intraday recommendation.

- Selling all 80 units does not prove demand was exactly 80; customers may have arrived after stockout. Record sellout time and observed unmet requests where possible.
- Filipino, Cebuano, and mixed-language voice input are promising, but reliable language support should only be claimed after testing.
- Food safety cannot be established by an AI guess or merchant checkbox. If required handling information is missing, do not recommend resale or carryover.

6. Differentiation

Differentiated workflow, not a claim of global uniqueness

Positioning
Enterprise-style production planning, simplified for Philippine small food businesses that may have limited data and no integrated POS.

Product	Existing strength	Overlap	Tantify difference
Peddlr	POS, inventory, expenses, reports, offline	Records what happened	Primary job is deciding what to prepare next
iCost	Recipe costing, inventory, pricing/analytics	Food-business economics	Costing supports the production decision instead of being the core
KwentaPOS	Bakery POS, recipes, ingredients, offline	Bakery operations	Can coexist with POS; focuses on preparation quantity/timing
ClearCOGS	Restaurant prep forecasting from POS data	Very close on how much to prep	POS-light, lower-data workflow for smaller Philippine operators
Guac	Fresh-food demand forecasting / production planning	Very close on forecasting	Microbusiness-first positioning and simple input path
Too Good To Go	Surplus/expiry/markdown/ marketplace tools	Leftover recovery	Recovery is secondary to production prevention; no marketplace at launch

What Tantify combines

- Simple manual, voice, or photo-assisted records.
- Preorders + recent sales + budget/batch/ingredient/capacity constraints in one recommendation.
- Explicit stockout tracking so sold-out days do not teach the model the wrong demand.
- Midday reassessment instead of only next-day forecasting.
- Owner approval and understandable explanations.
- Leftover-risk action before closing, then feedback into the next cycle.

Do not claim
"First in the world," "competitors cannot do this," or "AI is the moat." The defensible value must come from workflow fit, trusted merchant data, measurable outcomes, retention, distribution, and integrations.

7. MVP and Prototype

Build one complete decision cycle, not a broad platform

Module	Minimum behavior	Why it matters
Business/product setup	Products, prices, recipes/yields, batch sizes, optional capacity	Defines economics and constraints
Quick daily log	Made, sold, leftover/discarded, stockout	Creates usable history with low burden
Preorders	Confirmed quantity by date/product	Protects committed demand
Planner	Recommended quantity/range with explanation	Core product value
Budget planner	Feasible mix under purchasing limit	Shows working-capital value
Midday update	Remaining stock / transaction checkpoint	Supports batch timing decisions
Recovery options	Markdown, bundle, donation/discard where eligible	Protects value after production
Outcome review	Actual vs recommended; overrides and trends	Shows learning and measurable value

Prototype screens

- 1. Onboarding / products / recipe or cost / batch size.
- 2. Quick record: made, sold, leftover, discarded, sold out.
- 3. Tomorrow's plan: preorders, budget, ingredients, and proposed quantities.
- 4. Owner approval: adjust quantity and record reason.
- 5. Midday update: remaining stock and conditional next-batch suggestion.
- 6. Outcome review: what happened, leftover/stockout trend, and financial interpretation.

Optional polish

If time permits, add one voice-input demonstration that converts a natural-language record into draft structured fields and requires owner confirmation.

Do not build yet

Full POS, payment custody, consumer marketplace, tax invoicing, automatic food-safety decisions, complex multi-branch integrations, or advanced AI claims.

8. Business Model and Investor Logic

Commercial story: money protected, not AI

Stage	Offer	Purpose
Pilot	Assisted setup, daily records, planning	Prove value and data feasibility
Single-business subscription	Recommendations, budget planning, alerts, outcome review	Test paid retention
Team / branch plan	Roles, shared products, branch planning, consolidated purchasing	Expand revenue within growing customers
Integrations later	POS and order-system connections	Reduce input effort and support larger accounts

Test price

P299/month may be used as an experiment because local business tools already use similar price points. It is not validated for Tantify.

Value metrics

Metric	What it tells us
Unsold quantity / production	Whether overproduction is changing
Discarded quantity	Whether actual waste is changing
Stockout frequency and timing	Whether lower production is causing shortages
Revenue minus defined variable costs	Whether operating contribution is improving
Daily recording time	Whether the workflow is practical
Recommendation use / overrides	Whether owners find the decision useful
Paid conversion / renewal	Whether value is strong enough to support a business

Investor questions Tantify must eventually answer

- How much does a qualified merchant actually lose from production mistakes?
- Does Tantify reduce unsold output without materially increasing stockouts?
- How many minutes per day does data entry take?
- Do merchants keep using recommendations after novelty wears off?
- How many pay and renew after the trial?
- Can customer acquisition and support costs be recovered from subscription margin?
- What prevents a POS provider from copying the feature?

9. Go-to-Market and Validation

Use real merchant behavior as the filter

Marketing message

Primary hook

"Not sure how much to prepare tomorrow?" Tantify learns from what you made, sold, had left, and sold out - then helps you plan the next batch.

Channel / tactic	How to use it
Direct merchant visits	Ask about yesterday's leftovers and stockouts; demonstrate with their own numbers.
Free trial	Let merchants record 1-2 weeks, then show patterns before asking them to pay.
Facebook / TikTok	Short peso-based examples: made vs sold vs remaining, then the next-day decision.
Local food-business groups	Reach bakeries, carinderias, stalls, cafes, and MSME communities.
Referral	Merchant invites another business; use trial extension only if economics support it.
Partners later	Negosyo Centers, coops, food associations, culinary schools, suppliers, POS providers.
Success stories	Use measured outcomes as the strongest advertisement.

Validation plan

- Week 1: 15-20 discovery interviews across relevant segments. Collect recent leftovers, sellouts, decision method, budget constraints, and current records.
- Week 2: onboard up to 10 pilot merchants; measure setup time and data quality.
- Weeks 3-4: observe baseline production, leftovers, stockouts, and recording burden without recommendations.
- Weeks 5-6: turn recommendations on; track adoption, overrides, unsold ratio, stockouts, and contribution.
- After trial: offer a real paid subscription; measure conversion, renewal, and cancellation reasons.

Decision rule

If merchants do not lose enough from production mistakes to care about "what should I prepare next?", do not rescue the idea by adding more dashboards, AI, or marketplace features. Pivot.

10. INNOVATHON Fit and 4-Minute Pitch

Keep the story focused on one merchant decision

Judging criterion	Weight	What Tantify should show
Problem understanding	25%	Specific merchant pain supported by interviews/observation or clearly labeled secondary evidence
Feasibility & scalability	25%	Focused prototype, low-data behavior, realistic staged integrations
Projected impact	25%	Waste, stockout, working-capital, and financial measures
Implementation plan	15%	Pilot design, data needs, validation gates, next steps
Presentation	10%	One clear customer story and understandable demonstration

Suggested 4-minute flow

Time	Pitch content
0:00-0:35	Small food sellers commit cash before knowing demand. Too much becomes leftover value; too little becomes a stockout.
0:35-1:05	Define the best-fit behavior: repeat production, uncertain demand, limited selling window, measurable outcomes.
1:05-2:15	Demo one scenario: history + preorders + budget/constraints -> plan -> owner approval -> midday update -> next-batch/recovery decision.
2:15-2:50	Differentiate honestly: POS/costing and forecasting tools exist; Tantify simplifies the workflow for small Philippine operators.
2:50-3:25	Show measurable value: unsold quantity, stockouts, recording time, working capital, contribution, and paid conversion.
3:25-4:00	Scalability: start with the highest-pain segment, then expand to adjacent food businesses and integrations.

Opening line

“Every food business has a tantsa - how much to cook, bake, or prepare. The problem is that this tantsa often depends on memory and instinct. Tantify turns that judgment into a practical, data-supported production decision.”

11. Hard Judge Questions

Short, defensible answers

Question	Defensible answer
Is it new?	Not as a technology category. The innovation is the simplified low-data workflow that combines production planning, budget/batch constraints, intraday reassessment, recovery, and next-cycle learning for small Philippine operators.
Why not Peddlr / iCost / KwentaPOS?	Those tools solve valuable POS, costing, and inventory needs. Tantify's primary job is deciding what, how much, and when to prepare.
ClearCOGS / Guac already forecast prep.	Yes. That validates the category. Tantify tests a POS-light, low-data workflow for smaller Philippine food businesses.
What if there is no history?	Start with owner baseline, confirmed orders, budget, and known constraints; show uncertainty until enough data exists.
What if you cause a stockout?	The owner approves every plan; use ranges/buffers and explicitly track sellout timing and overrides.
Why the budget feature?	For microbusinesses, the feasible decision may be constrained by tomorrow's cash, not just expected demand.
Who pays?	The owner/operator. Any price survives only if measured value repeatedly exceeds the fee and effort.
Why Food Security?	It targets avoidable prepared-food loss and production efficiency; measure merchant-level outcomes rather than claim it solves hunger.

Core pitch message

Tantify helps small food-business owners turn limited cash, simple records, and uncertain demand into a practical daily preparation plan.

12. Risks, Boundaries, and Final Position

What can invalidate the idea

Top risks

- The pain may not be frequent or expensive enough in the first segment.
- Manual data entry may be too burdensome; voice/photo capture may still be inaccurate.
- Poor recommendations may increase stockouts.
- Competitors may add similar planning features.
- Food-safety mistakes could create serious liability.
- Savings claims may be misleading if counterfactuals are double counted.
- The test subscription price may not convert despite comparable local software pricing.
- The name Tantify requires proper trademark clearance before commercial use.
- Multi-branch purchasing and complex integrations can distract from validating the core decision.

Measurement boundaries

- Do not count the full selling price of discarded food as money saved.
- Do not count the same unit as both prevented waste and recovered surplus.
- Weather, events, opening hours, and price changes can affect outcomes; simple before/after comparison does not prove causation.
- Keep actual observations separate from modeled estimates and illustrative scenarios.

Final position

Proceed with Tantify as a production-decision companion. Keep production planning at the heart of the product; keep leftover recovery as a secondary layer; use Kasya sa Puhunan, batch timing, voice/photo capture, and intraday updates only to strengthen the core decision.

Brand

TANTIFY - Turn Tantsa Into Better Production Decisions.

Campaign line: Guess Less. Prepare Smarter. Earn More.

Name logic: tantsa + quantify.

13. Reference Notes and Evidence Status

Source basis preserved from the previous SaktoServe guide

- [E1] INNOVATHON 2026 official event agenda supplied by the user.
- [S1] Philippine Statistics Authority, 2024 ASPBI - Accommodation and Food Service Activities, final results (2026).
- [S2] PSA Davao Region establishment statistics previously reviewed in concept research.
- [S3] Philippine food-service research previously reviewed identifying overproduction/spoilage among waste causes.
- [S4] Davao/local bakery operations research previously reviewed discussing demand forecasting and production scheduling.
- [C1] Peddlr - public POS/inventory/offline features.
- [C2] iCost - public food-costing/inventory/pricing features and a PHP 299 Plus price point previously reviewed.
- [C3] KwentaPOS - public bakery POS/recipe/inventory features and a PHP 299 Pro price point previously reviewed.
- [C4] ClearCOGS - restaurant preparation forecasting from POS data.
- [C5] Guac - fresh-food demand forecasting and production planning.
- [C6] Too Good To Go Platform - expiry/markdown/marketplace/donation features.

Evidence status

Public sources and competitor offerings support the problem category and competitive context, but they do not establish local customer demand, merchant loss frequency, forecast lift, willingness to pay, retention, or unit economics. Those remain validation tasks.

All example quantities, savings, and pricing assumptions in this guide are illustrative unless attributed to a source. Public competitor features were not independently benchmarked through hands-on trials. This document merges the previous SaktoServe Complete Concept & Pitch Guide with the user-supplied revised concept, updates the brand from Tantsa to TANTIFY, and retains the added budget, intraday, multimodal-input, cold-start, and measurement refinements.
